

# Robust social planner with a single capital stock: notes

March 4, 2018

## 1 Adjustment cost model

Let  $K_t$  be capital and  $I_t$  be investment and  $C_t$  be capital. Suppose that

$$K_{t+1} = K_t \exp \left[ \alpha_k + \left( \frac{I_t}{K_t} \right) - \phi \left( \frac{I_t}{K_t} \right)^2 \right] \exp \left( \beta Z_t + \sigma_k \cdot W_{t+1} - \frac{1}{2} |\sigma_k|^2 \right)$$

In addition:

$$C_t + I_t = AK_t$$

where  $A$  is a fixed parameter. The process  $Z_t$  is an AR1 normalized to have mean zero:

$$Z_{t+1} = \alpha_z + \exp(-\xi) Z_t + \sigma_z \cdot W_{t+1}$$

where  $|\xi| < 1$ .

Transform variables:

$$\log K_{t+1} = \log K_t + \alpha_k + \left( \frac{I_t}{K_t} \right) - \phi \left( \frac{I_t}{K_t} \right)^2 + \beta Z_t + -\frac{1}{2} |\sigma_k|^2 + \sigma_k \cdot W_{t+1}$$

and

$$\frac{C_t}{K_t} + \frac{I_t}{K_t} = A$$

Assume the period utility function is:

$$(1 - \beta) \log C_t = (1 - \beta) (\log C_t - \log K_t) + (1 - \beta) \log K_t$$

where  $0 < \beta < 1$ . The  $1 - \beta$  scaling is done for convenience. Guess a date  $t$  continuation

value:

$$V_t = \log K_t + f(Z_t)$$

where under expected utility:

$$V_t = (1 - \beta) \log C_t + \beta E(V_{t+1} | \mathcal{F}_t)$$

and where  $\frac{C_t}{K_t}$  and  $\frac{I_t}{K_t}$  are chosen optimally subject to the constraint and the capital evolution equation.

Use the following parameters:

$$\begin{aligned} \alpha_y &= .373 & \beta &= 1 \\ \alpha_z &= 0 & \xi &= .017 \end{aligned}$$

$$\sigma = \begin{bmatrix} (\sigma_y)' \\ (\sigma_z)' \end{bmatrix} = \begin{bmatrix} .481 & 0 \\ .012 & .027 \end{bmatrix} \quad (1)$$

where  $\sigma_y = \sigma_k$  and

$$\alpha_y = \alpha_k + \left( \frac{I_t}{K_t} \right) - \phi \left( \frac{I_t}{K_t} \right)^2 - \frac{1}{2} |\sigma_k|^2.$$

is the implied growth rate for consumption net of the contribution from  $Z$ . (The  $\frac{I}{K}$  ratio turns out to be constant in this model.) Note: with this scaling one of the shocks has permanent consequences and the other is temporary.

Verify that both are state independent and that  $f$  is affine in the realized value  $z$  of  $Z_t$ .

Repeat the same calculation with a risk-sensitive or robustness adjustment for the the continuation value. What impact does risk sensitivity or robustness concern have on  $\frac{C_t}{K_t}$  and  $\frac{I_t}{K_t}$  for this economy? The continuation value under robustness is:

$$V_t = (1 - \beta) \log C_t - \beta \theta \log E \left[ \exp \left( -\frac{1}{\theta} V_{t+1} \right) | \mathcal{F}_t \right]$$

## 2 Permanent income model

We use a model of the type suggested by Hall and Flavin to capture a version of Friedman's permanent income model of consumption. Let  $\{Y_t\}$  be the logarithm of an exogenous nonfinancial income process that is governed by an additive functional

$$Y_{t+1} - Y_t = D \cdot X_t + F_y \cdot W_{t+1} + \nu$$

where

$$X_{t+1} = AX_t + BW_{t+1}$$

and  $A$  is a stable matrix. Define  $Y_t^0 = \bar{y}_0 + t\nu$  and

$$Y_{t+1}^1 - Y_t^1 = D \cdot X_t + F_y \cdot W_{t+1}.$$

Let  $\hat{K}_t$  be an asset stock that can be negative, meaning that we allow indebtedness. Combine an "asset return"  $\exp(\rho)\hat{K}_t$  and a time  $t$  exogenous nonfinancial income to deduce that the asset stock evolves according to

$$\hat{K}_{t+1} + \exp(\hat{C}_t) = \exp(\rho)\hat{K}_t + \exp(Y_t), \quad (2)$$

where  $\hat{C}_t$  is the logarithm of consumption at date  $t$  and  $\rho$  parameterizes an exogenous constant rate of return on assets. It is convenient to scale variables by nonfinancial income, so we define  $C_t = \hat{C}_t - Y_t$  and  $K_t = \frac{\hat{K}_t}{\exp(Y_t)}$ . Divide both sides of equation (2) by  $\exp(Y_t)$  to obtain

$$K_{t+1} \exp(Y_{t+1} - Y_t) + \exp(C_t) = \exp(\rho)K_t + 1. \quad (3)$$

A representative consumer with time separable preferences, logarithmic one period utility of consumption, and subjective discount rate  $\delta$  chooses a consumption process that respects the Euler equation

$$\exp(-\delta + \rho)E \left[ \exp(\hat{C}_t - \hat{C}_{t+1}) | X_t \right] = 1,$$

or equivalently

$$\exp(-\delta + \rho)E \left[ \exp(C_t - C_{t+1} + Y_t - Y_{t+1}) | X_t \right] = 1.$$

We assume that

$$\exp(-\delta + \rho - \nu) = 1,$$

a restriction that supports steady states in which the log consumption-log income ratio equals  $\bar{c}$ .

## 2.1 Steady state

Steady state means of asymptotically stationary components of  $(C_t, K_t)$  must satisfy

$$\bar{k} \exp(\nu) + \exp(\bar{c}) = \exp(\rho) \bar{k} + 1$$

or equivalently

$$\exp(\bar{c}) = [\exp(\rho) - \exp(\nu)] \bar{k} + 1,$$

where we assume that  $\rho > \nu$ . Notice that we are free to set  $\bar{k}$ . For convenience, in what follows we assume that  $\bar{k} = 0$  and hence that  $\exp(\bar{c}) = 1$ .

## 2.2 First-order approximation

We take a first-order small-noise approximation that scales  $W_{t+1}$  by  $\mathbf{q}$  and let  $\mathbf{q}$  tend to zero. The processes with superscripts 1 are effectively first-order derivatives of the original processes with respect to  $\mathbf{q}$  evaluated at  $\mathbf{q} = 1$ :

$$\begin{aligned} K_{t+1}^1 \exp(\nu) + \bar{k} \exp(\nu) (Y_{t+1}^1 - Y_t^1) + \exp(\bar{c}) C_t^1 \\ = \exp(\rho) K_t^1. \end{aligned}$$

Then the restriction

$$K_{t+1}^1 = \exp(\rho - \nu) K_t^1 - \bar{k} (Y_{t+1}^1 - Y_t^1) - \exp(\bar{c} - \nu) \exp(\bar{c}) C_t^1 \quad (4)$$

and  $\bar{k} = 0$  make this equation become

$$K_{t+1}^1 = \exp(\rho - \nu) K_t^1 - \exp(-\nu) C_t^1 \quad (5)$$

Furthermore, a first-order approximation to the Euler equation is

$$E[C_{t+1}^1 + Y_{t+1}^1 | \mathcal{F}_t] = C_t^1 + Y_t^1$$

We can solve equation (4) forward, with or without taking conditional expectations of all time indexed variables.<sup>1</sup> To derive a decision rule for consumption that solves a representative agent planning problem, we solve forward and take conditional expectations:

$$\begin{aligned} \exp(\nu)K_t^1 &= \sum_{j=0}^{\infty} \lambda^{j+1} E(C_{t+j}^1 + Y_{t+j}^1 | \mathcal{F}_t) - \sum_{j=0}^{\infty} \lambda^{j+1} E(Y_{t+j}^1 | \mathcal{F}_t) \\ &= \left( \frac{\lambda}{1-\lambda} \right) (C_t^1 + Y_t^1) - \left( \frac{\lambda}{1-\lambda} \right) \sum_{j=1}^{\infty} \lambda^j E(Y_{t+j}^1 - Y_{t+j-1}^1 | \mathcal{F}_t) - \left( \frac{\lambda}{1-\lambda} \right) Y_t^1 \\ &= \left( \frac{\lambda}{1-\lambda} \right) C_t^1 - \left( \frac{\lambda}{1-\lambda} \right) \sum_{j=1}^{\infty} \lambda^j E(Y_{t+j}^1 - Y_{t+j-1}^1 | \mathcal{F}_t) \end{aligned} \quad (6)$$

where  $\lambda = \exp(\nu - \rho)$ . Decision rule (6) implies that  $C_t^1$  and  $K_t^1$  are cointegrated with cointegrating vector  $\begin{bmatrix} 1 & [\exp(\nu) - \exp(\rho)] \end{bmatrix}$ .

From equation (6),

$$C_t^1 = \frac{\exp(-\nu)(1-\lambda)}{\lambda} K_t^1 + \exp(-\nu) \sum_{j=1}^{\infty} \lambda^j E(Y_{t+j}^1 - Y_{t+j-1}^1 | \mathcal{F}_t)$$

This links the log consumption-income ratio to the two income sources: financial income and non-financial income. The non-financial income contribution

$$\sum_{j=1}^{\infty} \lambda^j E(Y_{t+j}^1 - Y_{t+j-1}^1 | \mathcal{F}_t) = \lambda A (I - \lambda A)^{-1} X_t$$

Equation (6) corresponds to the solution of the planner's problem in the Hansen et al. (1999) economy without robustness (i.e., with their  $\sigma = 0$ ).

## 2.3 Impulse responses

We evaluate the decision rules for consumption and assets at the following nonfinancial income processes adapted from Hansen et al. (1999), who assumed two components for

---

<sup>1</sup>Cite a reference to one of many places where we have done this in other publications.

nonfinancial income. Let

$$X_{1,t+1}^1 = .704X_{1,t} + \begin{bmatrix} .144 & 0 \end{bmatrix} W_{t+1}$$

where  $Y_{1,t+1}^1 = Y_t^1 + X_{1,t+1}^1$ . To construct the second component, let

$$X_{2,t+1}^1 = X_{2,t}^1 - .154X_{2,t-1}^1 + \begin{bmatrix} 0 & .291 \end{bmatrix} W_{t+1}.$$

and construct  $Y_{2,t+1}^1 = X_{2,t+1}^1$ . Let  $Y_{t+1}^1 = (.01)Y_{1,t+1}^1 + (.01)Y_{2,t+1}^2$ .<sup>2</sup> We represent this  $\{Y_t\}$  process as an additive functional. Set  $\rho = .00663$  and  $\nu = .00373$ .

---

<sup>2</sup>We take income numbers from the first column of Table 2 of Hansen et al. (1999) with two exceptions. In Hansen et al. (1999), both income processes are stationary but one has an autoregressive root of .998. We set this to one here. This actually has a nontrivial impact on the consumption volatility, which Hansen et al. estimate in levels. We scale both innovation standard deviations by 1.33 to achieve a consumption growth rate volatility of .482 expressed as a percent (log differences multiplied by 100).

Figure 1: Impulse responses of log income to the two shock processes. Top panel: permanent shock. Bottom panel: transitory shock. Parameter settings from Hansen et al. (1999).

From Figure 1, the first shock has permanent consequences as is reflected by the limiting impulse response. The second has transitory implications as evident from the convergence of impulse responses to zero. The permanent shock cannot be approximately diversified over time, while, via investment or savings adjustments, the transitory shock can be. Under time separability, the responses are constant across horizons. The two consumption responses are:

$$\begin{aligned}\text{permanent shock} &= .482 \\ \text{transitory shock} &= .00383,\end{aligned}$$

(when multiplied by 100) which shows the dramatic difference induced by the endogenous consumption savings responses.

There is a sense in which responses to both shocks are present-value neutral. Consumption is allowed to differ from income; but discounted-by- $\lambda$  impulse responses for consumption and income should offset one another. As  $C_t^1$  is the first-order approximation to the log consumption/income ratio, the infinite discounted sum of the responses should be zero. Figure 2 computes the discounted sum over the alternative horizons in order to check how quickly the sum converges to zero. From the time scale, we see that the convergence is indeed slow.

Figure 2: Present value responses for the two shock processes. Top panel: permanent shock. Bottom panel: transitory shock. Parameter settings from Hansen et al. (1999).

## 2.4 Robustness

Now activate robustness as in Hansen-Sargent-Tallarini. We use the utility recursion:

$$V_t = [1 - \exp(-\delta)](C_t + Y_t) - \exp(-\delta)\xi \log E \left[ \exp \left( -\frac{1}{\xi} V_{t+1} \right) | \mathcal{F}_t \right]$$

where  $V_t$  is the date  $t$  continuation value. Setting  $\xi = \infty$  gives time-separable log utility. The parameter  $\xi$  is the inverse of the risk sensitivity parameter used in Hansen et al. (1999). The first-order approximation to a continuation value process in logarithms is of the form

$$V_t^1 = [1 - \exp(-\delta)](C_t^1 + Y_t^1) - \exp(-\delta)\xi \log E \left[ \exp \left( -\frac{1}{\xi} V_{t+1}^1 \right) | \mathcal{F}_t \right]$$

where  $F_c \cdot W_{t+1}$  gives the response of  $C_{t+1}^1$  to  $W_{t+1}$ . We maintain that the evolution for  $C_{t+1}^1 + Y_{t+1}^1$  is:

$$C_{t+1}^1 + Y_{t+1}^1 = C_t^1 + Y_t^1 + (F_c + F_y) \cdot W_{t+1} \quad (7)$$

Then

$$V_t^1 = C_t^1 + Y_t^1 - \frac{|F_c + F_y|^2}{2\xi}$$

Notice that  $(F_c + F_y) \cdot W_{t+1}$  denotes the exposure of  $V_{t+1}^1$  to shocks. Under the implied change of measure associated with the positive random variable

$$M_{t+1}^0 = \frac{\exp \left( -\frac{1}{\xi} V_{t+1}^1 \right)}{E \left[ \exp \left( -\frac{1}{\xi} V_{t+1}^1 \right) | \mathcal{F}_t \right]}$$

$W_{t+1}$  is normally distributed with mean  $-\frac{1}{\xi}(F_c + F_y)$  and covariance matrix  $I$ .

Thus, because a robust planner acts “as if” he is a nonrobust planner but one who takes conditional expectations with this distorted probability distribution instead of the benchmark distribution, the consumption Euler equation is now

$$\exp(-\delta + \rho - \nu) E \left[ M_{t+1}^0 (C_{t+1}^1 + Y_{t+1}^1) | \mathcal{F}_t \right] = C_t^1 + Y_t^1$$

Under the implied worst-case model, the expected growth rate in consumption is adjusted downward by:

$$-\frac{|F_c + F_y|^2}{\xi}$$

This would then impact the implied risk-free interest rate.

As an alternative, we follow Hansen et al. (1999) by fixing a target interest rate and adjusting  $\delta$  accordingly. To be consistent with evolution equation (7), we therefore assume:

$$\delta = \rho - \nu - \frac{|F_c + F_y|^2}{\xi}$$

This gives an affine in  $\frac{1}{\xi}$  counterpart to formula (28) in Hansen et al. (1999) with slope coefficient:  $-\frac{|F_c + F_y|^2}{2}$  as is depicted in Figure 3.

Figure 3: Subjective discount rates and robustness. This plot shows how to adjust the subjective discount rate  $\delta$  for a given value of  $\frac{1}{\xi}$  while leaving the implied riskless rate fixed.

The uncertainty price vector for the two shocks is:

$$-\frac{1}{\xi} (F_c + F_y) = -\frac{.01}{\xi} \begin{bmatrix} .482 \\ .00383 \end{bmatrix}$$

The exposure to the shock with permanent consequences requires much larger compensations as the robust planner fears the misspecification of that more.

### 3 Habit persistence

We aim now to construct a multiplicative-functional counterpart to HST's specification with habit persistence. (With different parameter values, the same specification could also capture durable consumption goods.)

Change preferences to be

$$V_t = [1 - \exp(-\delta)] \log U_t - \exp(-\delta) \xi \log E \left[ \exp \left( -\frac{1}{\xi} V_{t+1} \right) | \mathcal{F}_t \right]$$

where

$$\exp(H_{t+1} + Y_{t+1}) = \exp(-\psi) [\exp(H_t + Y_t)] + [1 - \exp(-\psi)] [\exp(C_t + Y_t)],$$

$$0 \leq \psi < 1,$$

$$\exp(U_t + Y_t) = v[\exp(C_t + Y_t), \exp(H_t + Y_t)],$$

and

$$v(c, h) = \left[ (1 - \alpha) c^{1-\eta} + \alpha h^{1-\eta} \right]^{\frac{1}{1-\eta}}.$$

The CES specification adopted here for  $v$  is able to capture either durability of consumption goods or habit persistence in preferences or both.

#### 3.1 H dynamics

Rewrite the  $H$  dynamics as

$$\exp(H_{t+1}) \exp(Y_{t+1} - Y_t) = \exp(-\psi) \exp(H_t) + [1 - \exp(-\psi)] \exp(C_t)$$

where we divided through by  $\exp(Y_t)$ .

The steady state counterpart

$$\exp(\bar{h}) \exp(\nu) = \exp(-\psi) \exp(\bar{h}) + [1 - \exp(-\psi)] \exp(\bar{c})$$

determines  $\bar{h}$ . The first-order approximation is

$$\exp(\nu) \exp(\bar{h}) [H_{t+1}^1 + (Y_{t+1}^1 - Y_t^1)] = \exp(-\psi) \exp(\bar{h}) H_t^1 + [1 - \exp(-\psi)] \exp(\bar{c}) C_t^1.$$

Equivalently,

$$H_{t+1}^1 = \exp(-\nu - \psi) H_t^1 + [\exp(-\nu) - \exp(-\psi - \nu)] \left[ \frac{\exp(\bar{c})}{\exp(\bar{h})} \right] C_t^1 - Y_{t+1}^1 + Y_t^1,$$

which after simplification becomes

$$H_{t+1}^1 = \exp(-\nu - \psi) H_t^1 + [1 - \exp(-\nu - \psi)] C_t^1 - Y_{t+1} + Y_t. \quad (8)$$

### 3.1.1 CES algebra

CES first derivatives:

$$\begin{aligned} mc &= (1 - \alpha) u^\eta c^{-\eta} \\ mh &= \alpha u^\eta h^{-\eta} \end{aligned}$$

Define

$$\bar{u} = \frac{1}{1 - \eta} \log \left( (1 - \alpha) \exp[(1 - \eta)\bar{c}] + \alpha \exp[(1 - \eta)\bar{h}] \right)$$

which is the steady-state version of  $U_t$ . The first-order approximation is:

$$U_t^1 = (1 - \alpha) \exp[(\eta - 1)(\bar{u} - \bar{c})] C_t^1 + \alpha \exp[(\eta - 1)(\bar{u} - \bar{h})] H_t^1 \quad (9)$$

### 3.1.2 Co-state evolution

There are two co-state equations and one set of first-order conditions for consumption:

$$\alpha \exp[(\eta - 1)(U_t + Y_t) - \eta(H_t + Y_t)] - \exp(\widehat{MH}_t) + \exp(-\delta - \psi) E \left[ \exp(\widehat{MH}_{t+1}) \mid \mathcal{F}_t \right] = 0$$

$$\begin{aligned} & (1 - \alpha) \exp[(\eta - 1)(U_t + Y_t) - \eta(C_t + Y_t)] \\ & + \exp(-\delta) [1 - \exp(-\psi)] E \left[ \exp(\widehat{MH}_{t+1}) \mid \mathcal{F}_t \right] - \exp(-\delta) E \left[ \exp(\widehat{MK}_{t+1}) \mid \mathcal{F}_t \right] = 0 \end{aligned}$$

$$\exp(-\delta + \rho) E \left[ \exp(\widehat{MK}_{t+1}) \mid \mathcal{F}_t \right] - \exp(\widehat{MK}_t) = 0.$$

Multiply by  $\exp(Y_t)$ :

$$\exp(-\delta - \psi) E [\exp (MH_{t+1} + Y_t - Y_{t+1}) | \mathcal{F}_t] = \exp (MH_t) - \alpha \exp [(\eta - 1)U_t - \eta H_t]$$

$$(1 - \alpha) \exp [(\eta - 1)U_t - \eta C_t] = \exp(-\delta) E [\exp (MK_{t+1} + Y_t - Y_{t+1}) | \mathcal{F}_t] \\ - \exp(-\delta)[1 - \exp(-\psi)] E [\exp (MH_{t+1} + Y_t - Y_{t+1}) | \mathcal{F}_t]$$

$$\exp(-\delta + \rho) E [\exp (MK_{t+1} + Y_t - Y_{t+1}) | \mathcal{F}_t] = \exp (MK_t)$$

### 3.1.3 Additional steady state calculations

$$\exp(-\delta - \psi - \nu) \exp (\overline{mh}) = \exp (\overline{mh}) - \alpha \exp [(\eta - 1)\bar{u} - \eta \bar{h}]$$

$$(1 - \alpha) \exp [(\eta - 1)\bar{u} - \eta \bar{c}] = \exp(-\delta - \nu) \exp (\overline{mk}) - \exp(-\delta - \nu)[1 - \exp(-\psi)] \exp (\overline{mh})$$

### 3.1.4 First-order approximation

$$\exp (-\delta - \psi - \nu + \overline{mh}) E [MH_{t+1}^1 + Y_t^1 - Y_{t+1}^1 | \mathcal{F}_t] \\ = \exp (\overline{mh}) MH_t^1 - \alpha \exp [(\eta - 1)\bar{u} - \eta \bar{h}] [(\eta - 1)U_t^1 - \eta H_t^1] \quad (10)$$

$$(1 - \alpha) \exp [(\eta - 1)\bar{u} - \eta \bar{c}] [(\eta - 1)U_t^1 - \eta C_t^1] \\ = \exp(-\delta - \nu) E [\exp(\overline{mk}) MK_{t+1}^1 - [1 - \exp(-\psi)] \exp(\overline{mh}) MH_{t+1}^1 | \mathcal{F}_t] \\ + \exp(-\delta - \nu) [\exp(\overline{mk}) - [1 - \exp(-\psi)] \exp(\overline{mh})] E (Y_t^1 - Y_{t+1}^1 | \mathcal{F}_t). \quad (11)$$

$$\exp(-\delta + \rho - \nu) E [MK_{t+1}^1 + (Y_t^1 - Y_{t+1}^1) | \mathcal{F}_t] = MK_t^1. \quad (12)$$

### 3.1.5 Solution strategy

One approach is to use the deflating subspace calculations described in Hansen and Sargent (2008, ch. 4).

1. Construct

$$Z_t^1 = \begin{bmatrix} MK_t^1 \\ MH_t^1 \\ K_t^1 \\ H_t^1 \\ X_t \end{bmatrix}$$

2. Take equations (9) and (11) and solve for  $U_t^1$  and  $C_t^1$  in terms of  $Z_t^1$  and  $Z_{t+1}^1$ .

3. Use equations (10), (11), (4), and (8) after substituting for  $U_t^1$ ,  $C_t^1$  and  $E(Y_{t+1}^1 - Y_t^1 | \mathcal{F}_1) = D \cdot X_t$  and form the system:

$$\mathbb{L}Z_{t+1}^1 = \mathbb{J}Z_t^1$$

where we initially zero out the shocks and use  $X_{t+1} = AX_t$ .

4. Now solve:

$$\mathbb{L} \begin{bmatrix} \mathbb{N}_{1,1} & \mathbb{N}_{1,2} \\ I & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} K_{t+1}^1 \\ H_{t+1}^1 \\ X_{t+1} \end{bmatrix} = \mathbb{J} \begin{bmatrix} \mathbb{N}_{1,1} & \mathbb{N}_{1,2} \\ I & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} K_t^1 \\ H_t^1 \\ X_t \end{bmatrix}$$

where the dynamics for

$$\begin{bmatrix} K_t^1 \\ H_t^1 \\ X_t \end{bmatrix}$$

are weakly stable. Form a generalized Schur decomposition. There will be a total of seven eigenvalues, three of which are associated with the exogenous dynamics. These three are all stable. There will be four eigenvalues associated with the endogenous dynamics, two of which are stable and two of which are unstable. One of the “endogenous” eigenvalues will be unity, and we will count this as (weakly) stable.

Form:

$$\begin{bmatrix} \mathbb{N}_{1,1} & \mathbb{N}_{1,2} \\ I & 0 \\ 0 & I \end{bmatrix}$$

by taking linear combinations of the five stable generalized eigenvalues. See Hansen and Sargent (2008, ch. 4) for elaboration.<sup>3</sup>

---

<sup>3</sup>This will involve employing an ordered Schur decomposition. Evan Anderson wrote one in Matlab. We

5. Add the shocks back to the  $X$  evolution.

### 3.1.6 Special case to check code

Set  $\alpha = 0$  and drop equation for  $MH_{t+1}$ . Thus there are six eigenvalues. Exogenous dynamics eigenvalues:

$$\begin{bmatrix} 0.809839 & 0.704 & 0.190161 \end{bmatrix}$$

Eigenvalue for  $H_t^1$  is  $\exp(-\nu - \psi)$ . Two endogenous eigenvalues that determine consumption and asset evolution. From (12) we and the restriction that

$$\exp(-\delta + \rho - \nu) = 1,$$

one of the eigenvalues should be identically one. There is an additional endogenous eigenvalue that is unstable and given by

$$\exp(\rho - \nu) = \exp(\delta) > 1.$$

---

can translate it to Julia. Evan's program is described in Hansen and Sargent (2008, ch. 4) and available at the website for the Matlab programs for that book.
